

# Package: hcci (via r-universe)

August 30, 2024

**Type** Package

**Title** Interval Estimation of Linear Models with Heteroskedasticity

**Version** 1.1.0

**Maintainer** Pedro Rafael Diniz Marinho <pedro.rafael.marinho@gmail.com>

**Description** Calculates the interval estimates for the parameters of linear models with heteroscedastic regression using bootstrap - (Wild Bootstrap) and double bootstrap-t (Wild Bootstrap). It is also possible to calculate confidence intervals using the percentile bootstrap and percentile bootstrap double. The package can calculate consistent estimates of the covariance matrix of the parameters of linear regression models with heteroscedasticity of unknown form. The package also provides a function to consistently calculate the covariance matrix of the parameters of linear models with heteroscedasticity of unknown form. The bootstrap methods exported by the package are based on the master's thesis of the first author, available at [https://raw.githubusercontent.com/prdm0/hcci/master/references/dissertacao\\_mestrado.pdf](https://raw.githubusercontent.com/prdm0/hcci/master/references/dissertacao_mestrado.pdf). The hcci package in previous versions was cited in the book VINOD, Hrishikesh D. Hands-on Intermediate Econometrics Using R: Templates for Learning Quantitative Methods and R Software. 2022, p. 441, ISBN 978-981-125-617-2 (hardcover). The simple bootstrap schemes are based on the works of Cribari-Neto F and Lima M. G. (2009) <https://doi.org/10.1080/00949650801935327>, while the double bootstrap schemes for the parameters that index the linear models with heteroscedasticity of unknown form are based on the works of Beran (1987) <https://doi.org/10.2307/2336685>. The use of bootstrap for the calculation of interval estimates in regression models with heteroscedasticity of unknown form from a weighting of the residuals was proposed by Wu (1986) <https://dx.doi.org/10.1214/aos/1176350142>. This bootstrap scheme is known as weighted or wild bootstrap.

HC

*Covariance Matrix - (HC0, HC2, HC3, HC4 and HC5)*

---

**Description**

This function calculates the covariance structure for heteroskedasticity linear regression model.

**Usage**

```
HC(model, method=4, k=0.7)
```

**Arguments**

model	Any object of class <code>lm</code> ;
method	Method HC that will be used to estimate the covariance structure. The argument method may be 0, 2, 3, 4 or 5;
k	Constant used by the method HC5. The suggestion of the authors is to use $k = 0.7$ .

**Value**

Returns an object of class `matrix` with the estimated covariance matrix.

**Author(s)**

Pedro Rafael Diniz Marinho <pedro.rafael.marinho@gmail.com>

**Examples**

```
data(schools)
datas = schools[-50L,]
y = datas$Expenditure
x = datas$Income/10000
model = lm(y ~ x)
HC(model, method=4)
```

---

Pboot

*Percentile Bootstrap Confidence Interval (Wild Bootstrap) - Linear Models Heteroskedasticity*

---

**Description**

This function calculates confidence intervals for the parameters in heteroskedasticity linear regression models. The intervals are estimated by bootstrap percentile.

**Usage**

```
Pboot(model, significance=0.05, double=FALSE, J=NULL, K=NULL,
      distribution="rademacher")
```

**Arguments**

model	Any object of class <code>lm</code> ;
significance	Significance level of the test. By default, the level of significance is <code>0.05</code> ;
double	If <code>double = TRUE</code> will be calculated intervals bootstrap <code>t</code> and double bootstrap <code>t</code> . The default is <code>double = FALSE</code> ;
J	Number of replicas of the first bootstrap;
K	Number of replicas of the second bootstrap;
distribution	Distribution of the random variable with mean zero and variance one. This random variable multiplies the error estimates in the generation of the samples. The argument <code>distribution</code> can be <code>rademacher</code> or <code>normal</code> (standard normal). The default is <code>distribution = rademacher</code> .

**Value**

A list with the following components:

beta	A numeric vector of length 2 containing the estimated coefficients of the model.
ci_lower_simple	A numeric vector of length 2 containing the lower bounds of the simple bootstrap confidence intervals for the coefficients.
ci_upper_simple	A numeric vector of length 2 containing the upper bounds of the simple bootstrap confidence intervals for the coefficients.
ci_lower_double	A logical vector of length 0 or 2. If <code>'double = FALSE'</code> , this will be a logical vector of length 0. If <code>'double = TRUE'</code> , this will be a numeric vector containing the lower bounds of the double bootstrap confidence intervals for the coefficients.
ci_upper_double	A logical vector of length 0 or 2. If <code>'double = FALSE'</code> , this will be a logical vector of length 0. If <code>'double = TRUE'</code> , this will be a numeric vector containing the upper bounds of the double bootstrap confidence intervals for the coefficients.
J	A numeric value indicating the number of bootstrap resamples used in the simple bootstrap.
K	A numeric value indicating the number of bootstrap resamples used in the double bootstrap, if <code>'double = TRUE'</code> .

## Examples

```
data(schools)
datas = schools[-50,]
y = datas$Expenditure
x = datas$Income/10000
model = lm(y ~ x)
Pboot(model=model, significance = 0.05, double = FALSE,
       J=1000, K = 100, distribution = "rademacher")
```

---

schools

*US Expenditures for Public Schools*

---

## Description

Per capita expenditure on public schools and per capita income by state in 1979.

## Usage

```
data(schools)
```

## Format

A data frame containing 51 observations of 2 variables.

**Expenditure** per capita expenditure on public schools,

**Income** per capita income.

---

Tboot	<i>Bootstrap-t Confidence Interval (Wild Bootstrap) - Linear Models Heteroskedasticity</i>
-------	--

---

## Description

This function calculates confidence intervals for the parameters in heteroskedasticity linear regression models. Ranges are estimated by the bootstrap-t and double bootstrap-t.

## Usage

```
Tboot(model, significance=0.05, hc=4, double=FALSE, J=NULL, K=NULL,
      distribution="rademacher")
```

## Arguments

model	Any object of class lm;
significance	Significance level of the test. By default, the level of significance is 0.05;
hc	Method HC that will be used to estimate the covariance structure. The argument method may be 0, 2, 3, 4 or 5;
double	If double = TRUE will be calculated intervals bootstrap-t and double bootstrap-t. The default is double = FALSE;
J	Number of replicas of the first bootstrap;
K	Number of replicas of the second bootstrap;
distribution	Distribution of the random variable with mean zero and variance one. This random variable multiplies the error estimates in the generation of the samples. The argument distribution can be rademacher or normal (standard normal). The default is distribution = rademacher.

## Value

A list with the following components:

beta	A numeric vector of length 2 containing the estimated coefficients of the model.
ci_lower_simple	A numeric vector of length 2 containing the lower bounds of the simple bootstrap confidence intervals for the coefficients.

ci_upper_simple	A numeric vector of length 2 containing the upper bounds of the simple bootstrap confidence intervals for the coefficients.
ci_lower_double	A logical vector of length 0 or 2. If 'double = FALSE', this will be a logical vector of length 0. If 'double = TRUE', this will be a numeric vector containing the lower bounds of the double bootstrap confidence intervals for the coefficients.
ci_upper_double	A logical vector of length 0 or 2. If 'double = FALSE', this will be a logical vector of length 0. If 'double = TRUE', this will be a numeric vector containing the upper bounds of the double bootstrap confidence intervals for the coefficients.
J	A numeric value indicating the number of bootstrap resamples used in the simple bootstrap.
K	A numeric value indicating the number of bootstrap resamples used in the double bootstrap, if 'double = TRUE'.
